

CLIMATE OUTLOOK FOR 2014 SUMMER SEASON IN SERBIA

May 21st 2014

Mean summer seasonal temperatures near or above the **climatological 1981-2010** average are more likely to occur than not. It should be noted that the highest positive anomaly is predicted in August.

Uncertainties in regional predictions are larger for precipitation than for temperature. In the mountains of the central and southern part of the country, summer season precipitation totals are likely to be above-average. In the rest of Serbia the probabilities for below-, near or above- normal conditions are approximately equal. It must be emphasized that it might be possible that some parts, especially mountainous ones, might locally have near- or above- normal summer season totals, due to episodes of the enhanced convection with high intensity rainfall. It should be noted that monthly precipitation sums during June in whole Serbia are likely to be above-average.

Probability for summer season temperature 2 m (%)	Probability for summer season precipitation (%)
Normal to Above normal (30, 35, 35) in whole Serbia	Above normal (40, 30, 30) in the mountainous region of the central and southern Serbia
	No predictive signal (33, 34, 33) in the rest of Serbia

The numbers in brackets from left to the right are related to the values of meteorological parameters for: below-, near- and above- normal.
